# Comments on BPS States in $N=4$ SYM

Xi Yin

Harvard University

based on C.-M. Chang, XY [1305.6314]

# The problem: count 1/16 BPS states in $N=4$ SYM

Earlier effort: Kinney, Maldacena, Minwalla, Raju, Berkooz,  
Reichmann, Simon, Kim, Lee, Grant, Grassi, ...

Why is it interesting?

There are large  $1/16$  BPS black holes  
in  $AdS_5$ .

Gutkowski, Reall, Chong, Cvetič, Lu, Pope, ...

There are large  $1/16$  BPS black holes in  $AdS_5$ .

And their entropies are not accounted for by the superconformal index (too small) nor by the number of BPS states in the free theory (too large).

[Kinney, Maldacena, Minwalla, Raju, '05]

We investigate this problem in weakly coupled  $N=4$  SYM, following [Grant, Grassi, Kim, Minwalla, '08]

1. We will identify all  $1/16$  BPS states in the  $N \rightarrow \infty$  limit, and match precisely with BPS multi-(super) graviton states. (This was done previously within certain subsectors, but not to full generality.)
2. We conjecture that all  $1/16$  BPS states at finite  $N$  are of the “multi-graviton” form. Some limited evidences via computerized enumeration of cohomology.
3. If our conjecture is correct, there are not enough states to account for the Bekenstein-Hawking entropy of BPS  $AdS_5$  black hole in supergravity - a sharp puzzle (more comments later).

# Formulation of the counting problem (I)

1. We want to find all  $1/16$  BPS local gauge invariant operators in  $N=4$  SYM (or equivalently,  $1/16$  BPS states on  $S^3$ ).
2. Pick one out of the 16 supercharges, call it  $Q$ . Its Hermitian conjugate in radial quantization is a special superconformal generator  $S$ .
3. The problem of counting  $1/16$  BPS states, i.e. states annihilated by  $Q$  and  $S$ , is equivalent to counting  $Q$ -cohomology ( $Q^2=0$ ).

## Formulation of the counting problem (II)

4. Suffices to work with letters that are 1/16 BPS in the free theory, i.e. ones that classically saturates the BPS bound,  $E=2J_L+H_1+H_2+H_3$ .

5. There are 4 bosonic letters of this type,

$$\varphi^n = \Phi^{4n}, \quad f = F_{++}, \quad (n=1,2,3)$$

and 5 fermionic letters of this type,

$$\psi_n = \Psi_{n+}, \quad \lambda_\alpha = \bar{\Psi}_\alpha^4, \quad (\alpha=\pm)$$

In addition, there are 2 covariant derivatives,

$$D_\alpha \equiv D_{+\alpha} .$$

## Formulation of the counting problem (III)

6. And constraints (equation of motion)

$$[D_\alpha, D_\beta] = \varepsilon_{\alpha\beta} f, \quad D_\alpha \lambda^\alpha = [\varphi^n, \psi_n].$$

7. Introduce commuting generating parameter  $z^\alpha$ . Write

$$\varphi^n(z) = \sum (z^\alpha D_\alpha)^k \varphi^n / k!, \quad \text{and similarly } \psi_n(z), f(z).$$

$$\text{Also, } \lambda(z) = \sum (z^\alpha D_\alpha)^k z^\beta \lambda_\beta / (k+1)!$$

8. Introduce anti-commuting generating parameter  $\theta_n$ .

Write

$$\Psi(z, \theta) = \lambda(z) + \theta_n \varphi^n(z) + \varepsilon^{nmp} \theta_n \theta_m \psi_p(z) + \theta_1 \theta_2 \theta_3 f(z).$$

## Formulation of the counting problem (IV)

9. Write  $\mathcal{Z} \equiv (z, \theta)$ . Q-action now takes the concise form

$$\{Q, \Psi(\mathcal{Z})\} = \Psi(\mathcal{Z})^2.$$

The only constraint on  $\Psi(\mathcal{Z})$  is

$$\Psi(0) = 0.$$

10. All gauge invariant operators of zero twist are made out of products of derivatives of  $\Psi(\mathcal{Z})$ , then restricted to  $\mathcal{Z}=0$ .

## Q-cohomology at $N=\infty$

They are products of single trace operators of the following form:

$$\prod_{\alpha} \partial_{z^{\alpha}}^{p_{\alpha}} \prod_n \partial_{\theta_n}^{q_n} \text{Tr} \left[ \prod_{\beta} (\partial_{z^{\beta}} \Psi)^{k_{\beta}} \prod_k (\partial_{\theta_k} \Psi)^{m_k} \right] \Big|_{z=\theta=0}$$

These precisely agree with the counting of free 1/16 BPS multi-gravitons in  $\text{AdS}_5 \times \text{S}^5$ .

## Finite N

There are trace relations among the operators that describe multi-graviton states in the infinite N limit. We will still refer to such operators as “multi-graviton” operators at finite N.

Are there **new** Q-cohomology classes due to trace relations?

Let's try...

For  $SU(N)$  theory, consider a fermionic letter  $X$  ( $X$  could be  $\partial_{z^+}\Psi$ , for instance). There is a trace relation of the form

$$\text{Tr}(X^{2N+1}) = \text{multi-trace.}$$

Now since  $Q\text{Tr}(\partial_{z^+}^2\Psi(\partial_{z^+}\Psi)^{2N-1}) = \text{Tr}((\partial_{z^+}\Psi)^{2N+1})$ , we can try to construct a new  $Q$ -cohomology class using the operator  $\text{Tr}(\partial_{z^+}^2\Psi(\partial_{z^+}\Psi)^{2N-1})$ . But, there is also a trace relation of the form

$$\text{Tr}(X^{2N-1}Y) = \text{multi-trace.}$$

In the end, no new  $Q$ -cohomology arises this way.

## Computer tests

Next, we try the most straightforward search of new cohomology classes, by enumerating  $Q$ -closed and  $Q$ -exact operators at low levels for  $SU(2)$ ,  $SU(3)$ ,  $SU(4)$  theories, and ask if all  $Q$ -cohomology classes are accounted for by the “multi-graviton” type operators.

This test is difficult to carry out to high levels, due to the computational complexity.

We did not find any new  $Q$ -cohomology class, in all cases tested.

# Some SU(2) and SU(3) examples

Here we label the operator by the charge vector that counts the number of  $\partial_z$ 's and  $\partial_{\theta}$ 's. The Q-cohomology in each charge sector is then graded by the number of  $\Psi$ 's, which ranges from 2 to the total number of  $\partial$ 's.

[2,1; 2,1,1]	(1, 0, 58, 0, 5, 0)	(1, 4, 81, 118, 114, 35)
[2,2; 1,1,1]	(4, 0, 67, 0, 1, 0)	(4, 6, 94, 92, 77, 20)
[2,2; 2,1,1]	(1, 0, 114, 0, 28, 0, 0)	(1, 4, 140, 242, 382, 237, 60)
[2,1; 2,2,1]	(0, 0, 77, 0, 42, 0, 0)	(0, 1, 95, 236, 465, 352, 100)
[1,1; 2,2,2]	(0, 0, 46, 0, 43, 0, 1)	(0, 0, 54, 191, 508, 515, 199)

In each case, no new cohomology class found.

We are led to **conjecture** that there are **no new** Q-cohomology classes, i.e. all 1/16 BPS operators are of the multi-graviton type, namely products of

$$\prod_{\alpha} \partial_{z^{\alpha}}^{p_{\alpha}} \prod_n \partial_{\theta_n}^{q_n} \text{Tr} \left[ \prod_{\beta} (\partial_{z^{\beta}} \Psi)^{k_{\beta}} \prod_k (\partial_{\theta_k} \Psi)^{m_k} \right] \Big|_{z=\theta=0}$$

In particular, this would imply that the number of 1/16 BPS operators of a given dimension in the SU(N) theory cannot be more than the number of such operators in the  $N \rightarrow \infty$  limit (free gravitons).

The entropy of the latter grows like  $S \sim E^{5/6}$ . One can also show that the entropy of “multi-graviton” operators at finite N is bounded by  $S \lesssim N^{1/3} E^{2/3}$ . Not enough states to account for large black hole entropy  $S \sim N^2$  when  $E \sim N^2$ .

## Some formality

In mathematical terms, our Q-cohomology classes are given by the relative Lie algebra cohomology (with coefficients in  $\mathbb{C}$ )

$$H^*(\mathfrak{g}_N, \mathfrak{sl}_N)$$

where  $\mathfrak{g}_N$  is the (infinite dimensional) Lie algebra of  $\mathbb{C}[z_+, z_-] \otimes \Lambda[\theta_1, \theta_2, \theta_3] \otimes \mathfrak{sl}_N$ , with the subalgebra  $\mathfrak{sl}_N \subset \mathfrak{g}_N$ . The grading of the cohomology is the degree in  $\Psi$ .

The inclusion  $\mathfrak{i}: \mathfrak{g}_{N-1} \rightarrow \mathfrak{g}_N$  induces a map on the cohomology

$$\mathfrak{i}^*: H^*(\mathfrak{g}_N, \mathfrak{sl}_N) \rightarrow H^*(\mathfrak{g}_{N-1}, \mathfrak{sl}_{N-1})$$

Our conjecture amounts to the statement that  $\mathfrak{i}^*$  is surjective, for all  $N$ .

## Puzzle

We are not producing the expected Bekenstein-Hawking entropy of large  $1/16$  BPS black hole from the counting of  $1/16$  BPS operators in  $N=4$  SYM at weak coupling.

## Possibility 1

The conjecture is false. Perhaps we did not test to high enough level in the  $SU(2)$  and  $SU(3)$  examples.

Should be possible to prove or disprove the conjecture by analyzing (a generalization of) the Hochschild-Serre spectral sequence associated with the embedding  $\mathfrak{g}_{N-1} \rightarrow \mathfrak{g}_N$ .

## Possibility 2

The number of  $1/16$  BPS states jump as the coupling increases. We see no evidence for this, however.

## Possibility 3

1/16 BPS black hole solutions in supergravity are destroyed by stringy corrections, and such black holes do not exist in the full string theory on  $AdS_5 \times S^5$ .

In any case, the existence of the  $1/16$  BPS black hole solutions in supergravity implies at least large number of near- $1/16$  BPS states at strong coupling, at dimension  $\sim N^2$ . [Berkooz, Reichmann '08]

This is a fascinating regime of  $N=4$  SYM to explore.
